Cost Pass-Through in the U.S. Coffee Industry

Ephraim Leibtag, Alice Nakamura, Emi Nakamura, and Dawit Zerom

A perennial issue in economics is the effect of changes in commodity prices on manufacturer and retail food prices. The traditional explanation is that the extent to which cost increases are “passed through” in a vertically organized production process depends on the market power of producers at each stage of production as well as the value added by each producer in the production process. The U.S. coffee industry is an excellent venue to study the issue of cost pass-through, since green coffee beans are important components of the marginal costs in this industry and are publicly traded commodities.

What Is the Issue?

This report uses unique data from the U.S. coffee industry to estimate how changes in commodity costs affect retail coffee prices. The results are relevant beyond the coffee industry, providing insight into how changes in commodity costs pass through to consumer and producer prices in other industries, too. “Cost pass-through” is a central issue in international economics since it determines how an economy responds to exchange rate adjustments as well as to changes in the prices of other imported commodities, such as oil.

What Did the Study Find?

Average manufacturer coffee prices dropped from 23 cents in 1997 to 17 cents per ounce in 2002. That drop corresponded with a fall in the coffee-bean share of the manufacturer price from 48 percent to 24 percent, while labor and other material costs rose from 15 percent to 32 percent.

The authors found that, on average, a 10-cent increase in green-coffee-bean prices per pound yields a 2-cent increase in both manufacturer and retail prices in the current quarter. If a cost change persists, it will be incorporated into manufacturer and retail prices approximately cent-for-cent with the commodity cost change. In addition, cross-sectional differences in prices are substantially larger at the retail than the wholesale level.

Since manufacturer prices adjust approximately one-for-one with commodity prices (rather than proportionally), the ratio between manufacturer prices and commodity

costs rises as commodity costs rise. The study does not find robust evidence that coffee prices respond more to increases than to decreases in costs.

How Was the Study Conducted?

An unusually rich collection of data on the ground-coffee industry was used to analyze the issue of cost pass-through. The data set included market-level average retail prices collected by Nielsen ScanTrack, market-level manufacturer prices collected by Promodata, and panel data collected by Nielsen Homescan to calculate the share of coffee by brand for each income level. Regression analysis was used to estimate the impact of changes in commodity prices on retail and manufacturer prices. These regressions are carried out for both absolute levels and in percentage terms. In addition, instrumental variable and fixed-effect methods were used to look at the manufacturer-retail price relationship and to analyze whether prices respond asymmetrically to cost increases and decreases.
