Abstract. Induction of apoptosis is one of the mechanisms of chemotherapeutic agents against breast cancer. In addition, recent studies have shown that diets containing polyphenolic components possess anticancer activities either in vitro or in vivo by inhibiting cell proliferation and inducing apoptosis. The aim of our study was to explore the effects of (-)-gossypol-enriched cottonseed oil [(-)-GPCSO], a polyphenolic compound, on the proliferation of the breast cancer cell line MCF-7 as well as primary cultured human breast cancer epithelial cells (PCHBCEC). We investigated whether the mechanism of the effects of (-)-GPCSO was mediated via the induction of cell apoptosis and the regulation of Bcl-2 gene expression at both the mRNA and protein levels. Our results showed that (-)-GPCSO inhibited the proliferation of MCF-7 and PCHBCEC in a dose-dependent manner. (-)-GPCSO (0.1 and 0.2%) induced DNA fragmentation in both MCF-7 cells and PCHBCEC. (-)-GPCSO suppressed the expression of Bcl-2 at both the mRNA and protein levels in MCF-7 cells and PCHBCEC in a dose-dependent fashion. Our results suggest that the growth inhibitory effect of (-)-GPCSO on MCF-7 and PCHBCEC is due, at least partially, to the induction of cell apoptosis, which is mediated by down-regulation of Bcl-2 expression at both the mRNA and protein levels. It might be possible for (-)-GPCSO to be developed as a novel chemotherapeutic agent for breast cancer patients.

Introduction

Breast cancer is one of the most frequently diagnosed female cancers and is second only to lung cancer as the most common cause of death among women 60 years of age or older (1). It is estimated that one in eight American women will develop breast cancer in her lifetime, and approximately one third of women with breast cancer develop metastases and ultimately die of the disease.

The molecular mechanisms underpinning the actions of cancer therapeutics are multi-factorial (2). One important mechanism is the activation of an apoptotic response via modulation of the expression of apoptosis regulatory proteins in cancer cells. Apoptosis, also known as programmed cell death, is a normal process of cell turnover that is characterized by nuclear condensation and degradation of DNA into oligonucleosomal fragments (3). It has been shown that the evasion of apoptosis by human cancer cells may result in drug resistance (4). The mechanisms by which most chemotherapeutic agents induce cell death are not well understood, although chemotherapy, radiotherapy and hormonal treatments appear to mediate their effects, in part, by inducing apoptosis (5-7). As the first line used in breast cancer chemotherapy, tamoxifen has been reported to induce apoptosis (8). It was reported that tamoxifen increases the apoptotic index (AI) in breast cancers expressing estrogen receptor, and there is a significant increase in the AI after 24 h of treatment with ICI 182 780, which is a pure estrogen antagonist without agonist activity (9). Zhang et al claimed that tamoxifen induced time- and concentration-dependent down-regulation of Bcl-2 at both the mRNA and protein levels, but tamoxifen did not affect Bax, an anti-apoptotic Bcl-2 family member, or p53 expression at the mRNA and protein levels (10). Regarding the second generation of selective estrogen receptor modulators, raloxifene has estrogen antagonist action in both the breast and uterus; it combines with E-cadherin/catenin to activate induction of apoptosis (11). The third generation of breast cancer chemotherapeutic agents, aromatase inhibitors, have recently been reported to be more effective than tamoxifen in treating breast cancer. Three aromatase inhibitors, letrozole, anastrozole and 4-hydroxyandrostenedione were shown to increase apoptosis by 14, 13 and 11%, respectively, after eight days of treatment in MCF-7 human breast cancer cells engineered to express aromatase (12).
As the first anti-apoptotic gene identified in 1988, Bcl-2 originally was recognized through its involvement in the t(14;18) chromosomal translocation characteristic of human follicular B-cell lymphoma (13). Hockenbery et al demonstrated that Bcl-2 is an inner mitochondrial membrane protein, and its overexpression blocks the apoptotic death of a pro-B- lymphocyte cell line (14). Several clinical investigations found that overexpression of Bcl-2 occurred in 40 to 80% of primary invasive breast carcinomas, depending on the methods of measurement and quantification (15-17). Furthermore, over-expression of Bcl-2 is associated with resistance to various anti-tumor agents (18). Down-regulation of Bcl-2 expression via antisense Bcl-2 decreased breast cancer cell viability (19). Gibson and his colleagues reported that it might be feasible to target Bcl-2 expression for the improvement of the outcome of current standard chemotherapies in breast cancer (20).

Gossypol (GP), a polyphenolic compound naturally occurring in cottonseed (21), was first identified as a male anti-fertility agent in China (22). Recently, GP was found to have anti-proliferative effects against a diversity of human cancer cell lines, such as breast, ovary, prostate and colon (23-26). Of the two main forms, (+)-GP has been found to be more potent than racemic GP (23). It was demonstrated that the anti-proliferative effect of GP is mediated via induction of cellular apoptosis. Teng claimed that GP induced apoptosis in rat spermatocytes mediated by biphasic regulation of c-fos protein (27). It has also been shown that less than 5 μM of GP induced DNA fragmentation in two human colon carcinoma cell lines HT29 and LoVo after exposures of 24 and 48 h (28). In addition, it was reported that GP has an apoptotic effect on human lymphocytes (29). Chang and his associates found that GP induced apoptosis in human alveolar lung cancer cell line A549 cells, mediated by up-regulation of Fas/FasL (30). Xu et al found that (+)-GP enhanced the response to radiation therapy resulting in tumor regression of human prostate cancer (31). GP has been shown to induce apoptosis in human promyelocytic leukemia HL-60 cells through the reactive oxygen species-independent mitochondrial dysfunction pathway (32). Oliver and his colleagues found that (+)-GP binds to the BH3-binding groove of Bcl-xL and Bcl-2 protein (33). It has been shown that milk from cows fed a GP-containing cottonseed meal significantly inhibited the growth of MCF-7, multidrug-resistant MCF-7/Adr and PCHBCEC due, at least partially, to the induction of apoptosis through its down-regulation of Bcl-2 at both the mRNA and protein levels in two types of cells.

Materials and methods

(-)-Gossypol-enriched cottonseed oil. (-)-GPCSO was kindly provided by the USDA Southern Regional Research Center, (New Orleans, LA) and contained ~65% (-)-GP, and 35% (+)-GP. It was diluted 50% as a stock solution in the same volume of dimethyl sulfoxide (DMSO) and stored at 4°C. Working stocks of (-)-GPCSO were freshly prepared before each experiment.

Cell culture. MCF-7 cells were cultured in phenol red-free high-calcium (1.05 mM CaCl2) Dulbecco's modified Eagle's medium and Ham's F12 medium (DMEM/F12, Atlanta Biologicals, Lawrenceville, GA) supplemented with 5% fetal bovine serum (FBS), and antibiotic-antimycotic (100 unit/ml penicillin G sodium, 100 mg/ml amphotericin B) (Gibco Cell Culture™). PCHBCEC were directly isolated from human breast cancer tissues obtained through the Tissue Procurement Program of The Ohio State University, Arthur G. James Cancer Hospital in Columbus, OH and then cultured in low calcium (0.04 mM CaCl2) DMEM/F12 supplemented with Chelex-100 (Bio-Rad Laboratories, Richmond, CA; cat. no. 142-2822)-treated FBS (10%) following a previously described protocol (23).

Non-radioactive cell proliferation assay. MCF-7 cells and PCHBCEC were cultured separately in 100 μl of either phenol red-free high-calcium DMEM/F12 medium supplemented with 5% FBS or low calcium DMEM/F12 medium supplemented with Chelex-100-treated 10% FBS in 96-well culture plates at an initial density of 5x10^3 viable cells/well. After being cultured overnight, the medium was replaced with either DMEM/F12 medium or low calcium DMEM/F12 medium supplemented with 0.2% bovine serum albumin (BSA) and cultured overnight. MCF-7 cells and PCHBCEC were treated with 0.025, 0.05, 0.1 and 0.2% (-)-GPCSO for 24 h. Final cell proliferation was determined by measuring the optical density at 490 nm according to the manufacturer's instructions. Briefly, 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2-H-tetrazolium (MTS) (Promega, Madison, WI; cat. no. G1111) was mixed with phenazine methosulfate (PMS) (Sigma, St. Louis, MO; cat. no. P9625-500MG) (20:1), and 20 μl of mixture was added to each well and incubated for 1.5 h. The color density was measured at 490 nm using a kinetic microplate reader (Molecular Devices Corp., Menlo Park, CA) and Softmax Pro software (version 2.1.1).

Cell morphology. MCF-7 cells (1x10^5) in DMEM/F12 medium containing 5% FBS were seeded in a 6-well plate. After a 24 h culture, the medium was replaced with DMEM/ F12 supplemented with dextran-coated charcoal (DCC) (dextran T-70, Pharmacia; activated charcoal, Sigma)-treated 5% FBS. The MCF-7 cells were treated with 0.1% (-)-GPCSO,
and photomicrographs were obtained following treatment of 0 and 24 h using a Olympus M021 microscope with a digital camera.

**DNA fragmentation analysis.** Cell culture and treatment were carried out as above. After 12 and 24 h treatment with vehicle control, 0.1 or 0.2% (-)-GPCSO, cells were collected, and the DNA fragmentation assay was performed using Quick Apoptotic DNA Ladder Detection Kit (Biovision, Mountain View, CA; cat. no. K120-50) (37). Samples were electrophoresed in a 1% agarose gel containing 0.5 mg/ml ethidium bromide. Images of the gel were obtained using a UV transilluminator and the Fujifilm LAS-3000 image system (Fujifilm Medical Systems USA, Inc., Stamford, CT).

**Cell treatment, total RNA extraction and reverse transcription-polymerase chain reaction.** MCF-7 cells or PCHBCEC were seeded separately in 5 ml of either DMEM/F12 medium supplemented with 5% FBS or low calcium DMEM/F12 supplemented with Chelex-100-stripped 10% FBS in 6-well culture plates at an initial density of 1x10^5 viable cells/well. For MCF-7 cells, the medium was replaced with DMEM/F12 medium supplemented with 5% DCC and Chelex-100-treated FBS. For PCHBCEC, the medium was replaced with low calcium DMEM/F12 supplemented with 10% DCC and Chelex-100-treated FBS. After 24 h, cells were treated with 0.05 and 0.1% (-)-GPCSO overnight, and then total RNA was extracted in 1 ml Trizol® Reagent (Invitrogen) following the manufacturer's instructions.

RT-PCR was performed in a Mastercycler (Eppendorf®). Briefly, after RNA concentrations were measured using the DU-70 spectrophotometer (Beckman Instruments Inc., Fullerton, CA, USA), 1 μg total RNA was reverse transcribed with 200 U M-MLV Reverse Transcriptase (Invitrogen) by incubating at 37°C for 50 min followed by 70°C for 15 min in the presence of 0.2 mM dNTP (stock solution 10 mM each dATP, dGTP, dCTP and dTTP at a neutral pH) (Invitrogen), 1 μM Random Hexamer (Amersham), 10 μl 5X First Strand Buffer (Invitrogen), 5 μl 0.1 M DTT (Invitrogen) and 1 μl RNase Inhibitor (Invitrogen) in a total volume of 50 μl. PCR conditions were optimized for the MgCl2 (Invitrogen) concentration, annealing temperature and cycle number for the amplification of Bcl-2 and 36B4 in a gradient Mastercycler. For Bcl-2, 2 μl of newly synthesized cDNA was used as a template for PCR. The PCR reaction mix consisted of 2.5 μl 10X PCR buffer (Invitrogen), 2.5 mM MgCl2, 1 U Platinum Taq DNA polymerase (Invitrogen), 0.24 μM each primer and pure water to a total volume of 25 μl. The reactions were incubated at 95°C for 5 min followed by thirty cycles of amplification consisting of denaturation at 95°C for 1 min, annealing at 60°C for 1 min, and elongation at 72°C for 1 min. A final incubation at 72°C for chain elongation was included. For 36B4, the reactions were incubated at 95°C for 5 min, then 30 cycles of amplification were performed with each cycle consisting of denaturation at 95°C for 1 min, annealing at 63°C for 1 min and extension at 72°C for 1 min. The primer sequences for Bcl-2 were 5’-GGT AAG TGG GGG AGG ATT GT-3’ (sense) and 5’-GGA GAA ATC AAA CAG AGG CC-3’ (antisense), and for the housekeeping gene, 36B4, the sequences were 5’-AAA CTG CTG CCT CAT ATC CG-3’ (sense) and 5’-TTT CAG CAA GTG GGA AGG TG-3’ (antisense). The final products were mixed with 2.5 μl 10X agarose gel sample buffer and 10 μl were loaded per well in a 1.5% agarose gel containing 1% ethidium bromide. The specific bands were quantified by ImageQuant software (Molecular Dynamics, Sunnyvale, CA). The results are presented as the ratio of Bcl-2 to 36B4.

**Western blot analysis.** Cell culture and treatment were carried out as described above. After 24 h of treatment, total cellular proteins were isolated using M-PER™ Mammalian Protein Extraction Reagent (Pierce, Rockford, IL), and protein concentrations were measured using the Bio-Rad DCC (Bio-Rad Laboratories, Hercules, CA) and transferred onto a PVDF membrane (Millipore Corp., Bedford, MA). The membrane was blocked in 5% non-fat dry milk in PBS containing 0.1% Tween-20 (PBS-T) at 4°C overnight. Immunoblotting was performed with primary antibody Bcl-2 (1:500 dilution sc-1517; Santa Cruz Biotechnology, Inc., CA, USA), or β-actin (1:1000 dilution sc-6299, Santa Cruz Biotechnology, Inc.) at room temperature for 1 h and then incubated with donkey anti-goat IgG-conjugated horseradish peroxidase (HRP) (1:1000 dilution, sc2002, Santa Cruz Biotechnology, Inc.) at room temperature for 1 h. Bcl-2 and β-actin proteins were visualized with a chemiluminescent detection system (ECL, Amersham Biosciences, Buckinghamshire, UK), and images were obtained using the Fujifilm LAS-3000 image system. The densities of specific bands were quantified by Multi-Gauge software (version 2.02). The results are presented as the relative protein expression by the ratio of Bcl-2 to β-actin.

**Statistical analysis.** The results for the MTS assay are presented as the mean ± standard deviation (SD) for four replicate culture wells as one treatment group. The results for the PCR reaction and Western blot analysis are presented as the mean ± SD for three replicates per group. Statistical analysis was performed using SAS for Windows (SAS Institute Inc. Cary, NC). Statistical differences were determined using the Student's t-test for independent samples. p-values <0.05 were considered to be statistically significant.

**Results**

**Inhibitory effects of (-)-GPCSO on proliferation of MCF-7 and PCHBCEC.** It was previously reported that (±)-GP and (-)-GP reduced the proliferation of primary cultured human breast cancer epithelial and stromal cells in a dose-dependent manner (23). In the present study, the effects of (-)-GPCSO on the proliferation of MCF-7 cells and PCHBCEC were evaluated by non-radioactive cell proliferation assay. (-)-GPCSO inhibited the growth of both MCF-7 cells and PCHBCEC in a dose-dependent manner (Fig. 1). In MCF-7 cells, 0.025, 0.05, 0.1 and 0.2% of (-)-GPCSO reduced cell growth to 15, 18, 47 and 69% of the control, respectively. In PCHBCEC, the same concentrations of (-)-GPCSO decreased cell growth to 6, 27, 30, 30% of the control, respectively.
(-)-GPCSO (0.05%) contains ~15 nM (-)-GP. These results suggest that (-)-GPCSO is a more potent inhibitor of human breast cancer cell proliferation. It was reported that the combination of (-)-GP with buthionine sulfoximine markedly inhibited the growth of MCF-7/Adr cells when compared with either inhibitor alone (38). Previous results from our laboratory revealed that the effective dose range for (-)-GPCSO against PC-3 cells, a prostate cancer cell line, was 524- to 2083-fold lower than that of chemically synthesized GP, which corresponds to an ~361,500- to 454,240-fold lower amount than the FDA-mandated limit for GP content in human food (450 ppm) (unpublished data).

Cell morphology. It was reported that 50-100 μM GP significantly induced apoptosis by 56-70% in lymphocytes (37). Cell morphology was evaluated under a microscope after treatment with 0.1% of (-)-GPCSO for 24 h. MCF-7 cells in the treatment group were shrunken and round in shape with condensed nuclei. In addition, cell-to-cell contact was lost. The percentage of abnormal cells was much larger in the 0.1% (-)-GPCSO-treated group compared with the vehicle-treated group (Fig. 2).

DNA fragmentation analysis. Konac and his colleagues claimed that 50 and 75 μM of GP induced DNA fragmentation in the human epidermoid laryngeal carcinoma cell line (HEp-2) after 6 h of exposure (39). We analyzed intranucleosomal DNA fragmentation induced by (-)-GPCSO in MCF-7 cells using the Quick Apoptotic DNA Ladder Detection Kit. After a 24 h treatment, the vehicle control had no low molecular weight DNA, whereas, MCF-7 cells treated with 0.1 and 0.2% (-)-GPCSO showed evidence of DNA fragmentation, a hallmark of apoptosis, that appeared after 24 h of exposure (Fig. 3).

(-)-GPCSO suppresses Bcl-2 mRNA expression in MCF-7 cells and PCHBCEC. In our laboratory, Huang et al found that 5 μM (-)-GP induced apoptosis in a prostate cancer cell line, DU-145, and decreased Bcl-2 and Bcl-xL mRNA expression (7). In order to determine whether (-)-GPCSO has a similar effect on human breast cancer cells, we evaluated Bcl-2 mRNA expression in MCF-7 cells and PCHBCEC by RT-PCR after treatment with 0.05 and 0.1% (-)-GPCSO. Our results demonstrated that (-)-GPCSO reduced Bcl-2 mRNA expression by 79, and 98% in MCF-7 cells, and 60 and 93% in PCHBCEC at 0.05 and 0.1% (-)-GPCSO after a 24 h treatment, as compared to their vehicle-treated groups (Fig. 4A and B).

(-)-GPCSO down-regulated Bcl-2 protein expression in MCF-7 cells and PCHBCEC. Xu and colleagues reported that (-)-GP inhibited Bcl-2 and Bcl-xL protein expression in...
PC-3 cells, a human prostate cancer cell line, and enhanced radiation-induced apoptosis in PC-3 prostate cancer in vitro and in vivo without augmenting toxicity (31). Bcl-2 protein expression was measured by Western blot analysis after cells were treated with different concentrations of (-)-GPCSO for 24 h. Our results revealed that (-)-GPCSO treatment decreased Bcl-2 protein expression by 38, 65, 82, and 88%, respectively, in MCF-7 cells (Fig. 4C), and 62, 71, 76, and 96%, respectively, in PCHBCEC (Fig. 4D), as compared to their vehicle-treated groups.

**Discussion**

The aim of the current study was to investigate whether (-)-GPCSO inhibits growth and promotes the apoptosis of human breast cancer cells. We were able to evaluate the inhibitory effects of (-)-GPCSO on the growth of MCF-7 cells and PCHBCEC, and this inhibitory effect appeared to be mediated by the induction of apoptosis in both cell types. Cell morphology results showed that MCF-7 cells were shrunken and became round in shape. Meanwhile, the condensation and aggregation of the nuclear chromatin into dense masses beneath the nuclear membrane appeared after treatment with 0.1% (-)-GPCSO for 24 h. The concentration of GP contained in (-)-GPCSO is much lower than that associated with the induction of apoptosis in human lymphocytes (37). This suggests that multiple components in (-)-GPCSO likely have a synergistic effect on the induction of apoptosis. Our results further illustrate that the apoptotic effect of (-)-GPCSO in breast cancer cells is mediated by the down-regulation of the Bcl-2 gene at both the mRNA and protein levels.

An understanding of the molecular mechanisms involved in the apoptosis induction and growth inhibition of (-)-GPCSO on
breast cancer cells is limited. Researchers have found that GP induces apoptosis in HL-60 cells through a reactive oxygen species-independent mitochondrial dysfunction pathway (32). Chang et al reported that the apoptotic effect of GP in A549 cells, an alveolar cell carcinoma of the lung, was mediated via up-regulation of membrane-bound as well as soluble FasL in A549 cells (30). Research has shown that induction of apoptosis by GP involves the regulation of Bcl-2 family members, and one of the most important members is pro-apoptotic Bcl-2. Overexpression of Bcl-2 was shown by several researchers to accelerate tumorigenesis and confer resistance to various therapeutic agents (40-42). Bcl-2 also has an effect on the cell cycle, and this effect is independent of its anti-apoptotic function (43,44). Studies have identified several mechanisms involved in the regulation of Bcl-2 expression in different types of cells. It has been reported that deletion of the BH4 region and point mutations in BH1 and BH2 within Bcl-2 abrogate both its anti-apoptotic activity and its effect on the lymphocyte cell cycle (45). Pro-apoptotic Bcl-2 family members include Bcl-2, Bcl-xL, and Bcl-w; there are four regions (BH1-4) that are most highly conserved among these members. BH1, BH2 and BH3 form a hydrophobic groove that can bind BH3 α-helix of an interacting BH3 only relative (46). Several researchers have proposed that certain small molecules, such as Bax, Bad, and Bcl-xL, with BH3-binding pocket affinity might function as Bcl-2 or Bcl-xL antagonists by blocking the heterodimerization of Bcl-2 with BH3-binding pocket affinity. The BH3 binding groove of Bcl-xL and Bcl-2 results in the inhibition of Bcl-2 and Bcl-xL function (33). Treatment of MCF-7 cells with basic fibroblast growth factor greatly inhibits MCF-7 cells with basic fibroblast growth factor (33). Treatment of MCF-7 cells with basic fibroblast growth factor greatly inhibits MCF-7 cell cycle, but also modulates Bcl-2 protein activity (50). Studies have identified several mechanisms involved in the regulation of Bcl-2 expression in different types of cells. It has been reported that deletion of the BH4 region and point mutations in BH1 and BH2 within Bcl-2 abrogate both its anti-apoptotic activity and its effect on the lymphocyte cell cycle (45). Pro-apoptotic Bcl-2 family members include Bcl-2, Bcl-xL, and Bcl-w; there are four regions (BH1-4) that are most highly conserved among these members. BH1, BH2 and BH3 form a hydrophobic groove that can bind BH3 α-helix of an interacting BH3 only relative (46).

In conclusion, our findings revealed that (-)-GPCSO has inhibitory effects on breast cancer cell growth, in part, due to the down-regulation of Bcl-2 gene expression at both the mRNA and protein levels, thus inducing apoptosis. The results suggest that (-)-GPCSO could be developed as a potent, less toxic chemotherapeutic agent, or used in conjunction with conventional chemotherapeutic agents to improve the efficacy of treatment in breast cancer patients.
