IRON CONTENT OF FOOD, Jacob Exler
Consumer Nutrition Center, Human Nutrition Information Service,
U.S. Department of Agriculture,
Hyattsville, Maryland 20782.
Home Economics Research Report Number 45

ABSTRACT

This publication presents newly compiled compositional data on the iron content of 277 foods commonly eaten in this country. Values are given only for food groups for which sections of revised Agriculture Handbook No. 8 have not yet been published. This provisional table will be superseded by subsequent sections of revised Handbook No. 8 as they are published.

The level of reliability of the values is given by the number of observations on which the mean values were based and the corresponding sample standard errors. Another measure of reliability, included in a table of food composition for the first time, is the confidence code. This code, based on a critical evaluation of the sources of data from which the mean values were derived, gives an indication of the confidence one can have in how closely the iron content of a food item is represented by the published value.

KEYWORDS: Iron content, foods, reliability, quality index, confidence code.

ACKNOWLEDGMENTS

The author gratefully acknowledges Susan Akridge for her technical assistance; the food group specialists of the Nutrient Data Research Group, Consumer Nutrition Center, for providing their collected data; and Wayne Wolf and Mary Moss, Nutrient Composition Laboratory, Beltsville Human Nutrition Research Center, Kent Stewart, Virginia Polytechnic Institute and State University, and Frank Hepburn, Nutrient Data Research Group, for their critical discussions in the development of the confidence codes and alternate means of nutrient data evaluation.

Iron Content of Food

Jacob Exler¹

INTRODUCTION

Many people in the United States have dietary intakes of iron, as estimated by using current food consumption tables, which are below the Recommended Dietary Allowance (RDA) (1,2)². To improve estimates of intakes and provide the basis for dietary guidance, more reliable data on the iron content of food are necessary.

This provisional table updates many of the iron values in Agriculture Handbook No. 8 (3) and in other U.S. Department of Agriculture publications by presenting newly compiled compositional data on the total iron content of foods commonly eaten in this country. Some of the earlier data were based on older, less reliable methods and some were based on relatively few samples. Also, because of the lack of sufficient analytical data, previously published values for iron in most meat products had been calculated as a function of protein as discussed in Appendix B of Agriculture Handbook No. 8 (3).

Iron values are given here for items in food groups for which sections of revised Agriculture Handbook No. 8 have not yet been published. These values were obtained from summaries compiled by the staff at the Consumer Nutrition Center, from data on file and from the USDA Nutrient Data Bank. The values reported here are summarized from data obtained by using improved, iron-specific analytical methods. Sources of data were the published literature, government and academic publications, and industrial and analytical laboratory reports.

For the iron content of items in those food groups for which sections of Handbook No. 8 have been revised and published [Dairy and Egg Products (4), Spices and Herbs (5), Baby Foods (6), Fats and Oils (7), Poultry Products (8), Soups, Sauces, and Gravies (9), and Sausages and Luncheon Meats (10), and Breakfast Cereals (11)], the appropriate sections should be consulted³.

This provisional table will be superseded by subsequent sections of revised Handbook No. 8 as they are published. The data in these future handbook sections will incorporate additional data received after preparation of this table. Therefore, some revision and additions to the iron values presented here should be anticipated in the future sections.

¹The author is a Research Chemist with the Consumer Nutrition Center, Human Nutrition Information Service.

²Underlined numbers in parentheses refer to Literature Cited, p. 5.

³The revised section on Fruits and Fruit Juices (AH-8-9) was published while this report was in press.

RELIABILITY OF VALUES

Many factors affect the iron content of foods. Content may vary with the time and location of harvest of the raw food. Some processing procedures remove iron from the food while others inadvertently add the nutrient by contamination. Differences in product formulation among manufacturers are another source of iron variability.

The available data and information for iron in the foods listed were not equally satisfactory for deriving values. The level of reliability of the values published in this table is indicated in several ways. Shown are the number of observations on which the mean value is based and the corresponding sample standard error (if the number of samples is greater than two). Also included is a confidence code.

Confidence codes are for use in food tables and in provisional nutrient tables. The purpose of these codes is to give a user an indication of the confidence he can have in the mean value given in the table. The codes are based on a critical evaluation of the data sets from which the mean values were derived. A quality index (0, 1, 2, or 3) for the data from each data set is assigned by using the criteria in table 1.

TABLE 1.--CRITERIA FOR QUALITY INDEX

Evaluation	Documentation of analytical method	Sample handling and appropriateness of analytical method	Quality control
0	None	Totally incorrect handling	No duplicates
1	Unpublished, but written	No documentation	Duplicate aliquots
2	Published, but modified	Reasonable, documented common technique	Duplicate samples
3	Complete published writeup	Extensive documented testing and appropriate method was used	Standard reference materials, spikes, recoveries, or blind duplicates

The lowest value for any criteria becomes the limiting quality index for the data from each data set. The sum of the quality indices from all the data sets used to obtain the overall mean value is the basis for selecting the confidence code for that mean value.

TABLE 2.--SELECTION AND MEANING OF CONFIDENCE CODES

Sum of quality indices	Confidence code	Meaning of confidence code
<u>>6</u>	a	The user can have confidence in the mean value.
3-5	b	The user can have some confidence in the mean value; however, some questions have been raised about the value or the way it was obtained.
1-2	c	There have been some serious questions raised about this value. It should be considered only as a best estimate of the level of this nutrient in this food.

The values reported in the table are the means of the data from two or more sources of data in which the mean values from each source do not differ from the overall mean by more than 30 percent of the overall mean. Other data are designated by an asterisk. A single asterisk (*) denotes that the data are from a single source. Two asterisks (**) denote that the data are from two or more sources, but the means differ from the overall means by more than 30 percent of the overall mean.

The data presented in this table, and in food composition tables in general, are intended to represent values of the nutrient content of food on a nationwide, year-round basis. The information on the reliability of each value in this table should be used to assess the confidence in how closely the iron content of a food sample is represented by that value.

DESCRIPTION OF THE TABLE

In this table, each food item is described and the mean iron content in milligrams per 100 grams of the edible portion of the food is given. The sample standard error and the total number of observations are also given. Next are the confidence code and asterisk(s), where appropriate. In the last column, the item numbers are given for those foods that correspond to items in the 1963 edition of Handbook No. 8. Dashes in this column denote there was no corresponding food or no value for iron was given in Handbook No. 8.

In general, foods that provided less than 2 percent of the U.S. Recommended Daily Allowance (U.S. RDA) for iron per serving were not included in the table. This corresponds to 0.36 milligram per serving and is the level below which, according to Federal

regulations (12), no specific value need be included on a nutrient label. Some foods with iron content below 0.36 milligram per serving were included in the table because values differ from these previously reported, because the food is consumed frequently or in large quantities, or to provide comparison with a closely related food.

"Enriched," as used in this table, refers only to iron and not to any other added nutrient. Foods with added iron must have the iron content per serving listed on the label expressed as the percent of the U.S. RDA. The following chart relating the percent of the U.S. RDA to milligrams is included to assist in estimating iron content from label claims:

<u>Percent</u> <u>U.S. RDA</u>	<u>Iron</u> <u>(mg)</u>
2	0.36
472
8	1.4
10	1.8
15	2.7
25	4.5
45	8.1
50	9.0
100	18.0

Actual iron content may be higher than that claimed on the label as a consequence of the compliance regulation (12).

**IRON
BIOAVAILABILITY**

The values in this table are for the total iron content of the food items and do not take into consideration the bioavailability of the iron in the foods. An estimate of the available iron in a meal can be calculated by the method of Monsen et al. (2, 13).

277	Vegetable juice, canned.....	.44	.03	13	b	2396

¹See p. 3 for explanation of confidence code.

²No standard error is given when the number of samples is two or less.

³Data for all canned items are for solids and liquid unless otherwise specified.

⁴This value is derived from analytical data. The new enrichment standard for flour (effective July 1983) will be 4.4 mg iron per 100 g.
